AMERICA'S STUPENDOUS TRAFFIC IN COAL

The coal trade of the United States is at a standstill. The present depression in the coal trade is due to the fact that the coal mines are not being worked at a sufficient rate to meet the demands of the consuming public. The coal trade is characterized by its cyclical nature, with periods of prosperity followed by periods of depression.

In 1912, the consumption of coal in the United States reached its peak, with over 100 million tons of coal consumed. However, in the following years, the coal trade experienced a significant decline. The decline was due to a number of factors, including the development of alternative energy sources, such as electricity and petroleum, and the economic depression of the early 1930s.

Despite the decline in coal consumption, the coal trade remains a significant industry in the United States. Coal is still an important source of energy, particularly in the generation of electricity. Coal mining remains a major employer in various regions of the country, and the coal trade continues to contribute to the economy of the United States.
